

# Class08 Machine Learning Mini Project

Yipeng Li

## Breast Cancer Project

Today we are going to explore some data from the university of Wisconsin Cancer Center on Breast biopsy data.

```
wisc.data <- read.csv("WisconsinCancer.csv", row.names=1)
head(wisc.data)
```

|          | diagnosis | radius_mean | texture_mean | perimeter_mean | area_mean |
|----------|-----------|-------------|--------------|----------------|-----------|
| 842302   | M         | 17.99       | 10.38        | 122.80         | 1001.0    |
| 842517   | M         | 20.57       | 17.77        | 132.90         | 1326.0    |

| 843786  |         |          | 0.12440  |         |         |

Q. How many patient samples are in this dataset.

```
nrow(wisc.data)
```

```
[1] 569
```

There are 569 patients in this dataset.

Q. How many cancer (M) and non cancer (B) samples are there?

```
table(wisc.data[,1])
```

```
  B    M  
357 212
```

Save the diagnosis for later use as a reference to compare how well we do with PCA etc.

```
diagnosis <- as.factor(wisc.data$diagnosis)  
#diagnosis
```

Now exclude the diagnosis column from the data

```
wiscn <- wisc.data[,-1]
```

Q. How many “dismensions,”variables”, “columns” are there in this dataset?

```
ncol(wiscn)
```

```
[1] 30
```

## Principal Component Analysis (PCA)

To perform PCA in R we can use the `prcomp()` function is takes as unput a numeric dataset and optional `scale=FALSE/TRUE` argument.

We generally always want to set `scale=TRUE` but let’s make sure by checking if the mean and standard deviation values are different across these 30 columns.

```
round(colMeans(wiscn))
```

|                |                     |                  |

```
attributes(pca)
```

```
$names  
[1] "sdev"      "rotation" "center"    "scale"     "x"  
  
$class  
[1] "prcomp"
```

```
plot(pca$x[,1], pca$x[,2], col=diagnosis)
```

```
library(ggplot2)  
  
x <- as.data.frame(pca$x)  
  
ggplot(x, aes(PC1,PC2, col=diagnosis))+  
  geom_point()
```

Q. How much variance is captured in the top 3 PCS

They capture 76%. of the total variance.

Q9. For the first principal component, what is the component of the loading vector (i.e. `wisc.pr$rotation[,1]`) for the feature `concave.points_mean`? This tells us how much this original feature contributes to the first PC.

```
pca$rotation["concave.points_mean",1]
```

```
[1] -0.2608538
```

```
attributes(pca)
```

```
$names
[1] "sdev"      "rotation" "center"    "scale"     "x"

$class
[1] "prcomp"
```

## Combine PCA results with clustering.

We can use our new PCA variables (i.e. the scores along the PCs contained in `pca$x`) as input for other methods such as clustering.

```
# Hclust needs a distance matrix as input
d <- dist(pca$x[,1:3])

hc <- hclust(d, method="ward.D2")
plot(hc)
```

### Cluster Dendrogram

d  
hclust (\*, "ward.D2")

To get our cluster membership vector we can use the `cutree()` function and specify a height (h) or number of groups (k).

```
grps <- cutree(hc, h=80)
table(grps)
```

```
grps
 1    2
203 366
```

```
table(diagnosis)
```

```
diagnosis
  B    M
357 212
```

I want to find out how many diagnosis “M” and “B” are in eac grp?

```
table(diagnosis, grps)
```

```
      grps
diagnosis  1  2
  B    24 333
  M   179  33
```

We can also plot our results using our clustering vector `grps`

```
#plot
plot(pca$x[,1], pca$x[,2], col=grps)
```

```
#ggplot
x <- as.data.frame(pca$x)

ggplot(x, aes(PC1,PC2, col=grps))+
  geom_point()
```

Q15. What is the specificity and sensitivity of our current results?

```
data <- table(diagnosis, grps)
data
```

```
      grps
diagnosis 1  2
B      24 333
M     179  33
```

```
#sensitivity TP/(TP+FN)
sensitivity <- data[2,1]/(data[2,1]+data[2,2])
sensitivity
```

```
[1] 0.8443396
```

```
#specificity TN/(TN+FN)
specificity <- data[1,2]/(data[1,1]+data[1,2])
specificity
```

```
[1] 0.9327731
```

## Prediction

Q16. Which of these new patients should we prioritize for follow up based on your results?

```
#url <- "new_samples.csv"
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(pca, newdata=new)
npc
```

Draw the plot

```
plot(pca$x[,1:2], col=grps)
points(npc[,1], npc[,2], col="blue", pch=16, cex=3)
text(npc[,1], npc[,2], c(1,2), col="white")
```

Based on the plot, the patient 1's data points are staying together, which means his/her cells are pretty similar, so it is likely normal. However, the Patient 2's data points are separate from each other, which means his/her cells are different from each other. This fits the feature of cancer. Thus, we should pay more attention to patient 2.
